AB The battery has a cathode comprising a **transition metal**-containing composite oxide as a cathode active mass, an anode containing a Li-intercalating anode active mass, a separator, and an nonaq. **electrolyte solution**; where the nonaq. **electrolyte solution** contains ≥1 1st additive selected from ethylene sulfite, propylene sulfite and propane sultone, and ≥1 2nd additive selected from maleic anhydride, vinylene carbonate, vinyl ethylene carbonate and LiBF₄, and the charging final voltage is set at 4.3-4.5V. The battery is manufactured by assembling an electrode group containing the cathode, the anode, and the separator, and the required **electrolyte soln.** into a battery case, and charging the battery at a high voltage ≥1 time.

AB The present invention is generally related to electrolytes containing anion receptor additives to enhance the power capability of lithium-ion batteries. The anion receptor of the present invention is a Lewis acid that can help to dissolve LiF in the passivation films of lithium-ion batteries. Accordingly, one aspect the invention provides electrolytes comprising a lithium salt; a polar **aprotic solvent**; and an anion receptor additive; and wherein the electrolyte solution is substantially non-aqueous. Further there are provided electrochem. devices employing the electrolyte and methods of making the electrolyte.

AB There are disclosed electrolytes comprising solns. of lithium salts with large anions in polar **aprotic solvents** with a particular concentration of background salts. The concentration of the background salts is selected to be equal or close to the concentration of a saturated solution of these salts in the **aprotic solvents** used. The electrolytes disclosed can be used in chemical sources of

elec. energy such as secondary cells and batteries comprising sulfur-based pos. active materials. The use of such electrolytes increases cycling efficiency and cycle life of the cells and batteries.

AB The solns. contain **aprotic solvents** and vinyladisulfones. The batteries,
 preferably secondary Li batteries, show less capacity drop after repeated charge
 discharge cycles by forming protective films of the vinyladisulfones on electrodes.

AB The electrolyte contains an aprotic solvent, a cyclic perfluoroalkyldisulfonimide anion, and a **transition metal** ion. The anion is preferably I, where R = linear or branched C2-4 perfluoroalkyl group, the **transition metal** is a **lanthanoide**, and the electrolyte may also contain other organic solvents. Another type of electrolyte contains an aprotic solvent, a Li salt, and a **transition metal** ion-cyclic

perfluoroalkyldisulfonimide anion complex II (n = 1-3, M = transition metal). The battery is a secondary Li battery.

AB An electrolyte for a nonaq. battery according to the present invention consists essentially of magnesium bistrifluoromethanesulfonimide. An **electrolytic solution** for a nonaq. battery according to the present invention includes the magnesium bistrifluoromethanesulfonimide, and an organic solvent such as a cyclic carbonate, a chain carbonate, a cyclic ether and a chain ether or an ordinary temperature molten salt having a m.p. of 60° or less in which the magnesium bistrifluoromethanesulfonimide is dissolved.

AB The present invention provides a technol. of inhibiting the decomposition of the solvent of the **electrolyte solution** for a secondary battery. Further, the present invention provides a technol. of prohibiting the resistance increase of a secondary battery and improving the storage properties such as improving the capacity retention ratio. An **electrolyte solution** comprising non-proton solvent and cyclic sulfonic ester including at least two **sulfonyl groups** may be used.

AB A reinforced polymeric ionic conductor, especially suitable as an electrolyte for rechargeable lithium batteries, consists of a polymer matrix, an ionic component, and a reinforcing agent, in which: (1) the matrix polymer is a polar solvating polymer, a non-solvating polymer containing ionic acids (e.g., grafted ionic acids), or a mixture of the above polymer(s) with an aprotic polar liquid, (2) the ionic component is selected from salts and acids, or has a anionic or cationic group covalently bonded to the polymer, or is an association of the two, and (3) the reinforcing agent is a cellulose or chitin derivative. Polymer matrixes are suitably homopolymers and copolymers of vinylidene difluoride, acrylonitrile, methacrylonitrile, alkyl acrylates and methacrylates, and ethylene oxide. The ionic acid groups on the polymer are preferably perfluorosulfonates or perfluorocarboxylates. Suitable aprotic polar liqs. include linear and cyclic ethers acetals, and carbonates; esters, nitriles, amides, sulfones, sulfolanes, alkylsulfamides, and halogenated hydrocarbons. Electron conductors can also be added to aid in the ionic conduction, such as acetylene black, carbon black, and insertable metals, metal oxides, and salts.

- AB Imidazolium based zwitterionic salts were prepared by 1-step reaction of 1-ethylimidazole and alkylsulfonates. The zwitterionic salts dissociate into ions but the ions do not migrate along with the potential gradient, making them suitable non-volatile polar solvents for guest salts. The zwitterionic salts obtained are 1-ethylimidazolium-3-n-propanesulfonate and -butanesulfonate. The salts were mixed with an equimolar amount of lithium bis(trifluoromethanesulfonyl)imide to provide a thermally stable electrolyte solution. This mixture was further mixed with the copolymer of vinylidene fluoride and hexafluoropropylene (Kynar Flex 2751), to prepare a polymer gel electrolyte. The polymer gel electrolytes have zwitterionic liquid content up to 80%; for mixts. with 66% zwitterionic liquid, the ionic conductivity is about 10^{-5} S/cm at 50° and showed no weight loss up to 390° in TGA studies.

AB A rechargeable hybrid battery/supercapacitor elec. storage system capable of providing high energy and high power densities comprises a neg. intercalation electrode and a pos. capacitor electrode comprising an anion-adsorbing component and a cation-intercalating material combined with a separator and elec.-conductive current collector elements to form a unitary cell structure. An **electrolyte solution** of a dissociable salt absorbed into the porous structure of the separator

provides complementary ion species which, supplemented by cations supplied from the pos. electrode intercalation material in order to increase the energy d. capability of the system, resp. reversibly intercalate into the neg. electrode and capacitively adsorb at the surface of the pos. electrode upon the application of charging current. The high d. stored elec. energy may be rapidly recovered at high power over extended periods upon demand of a utilizing device and may be equally rapidly restored to stable high energy capacity through numerous charging cycles.

AB The polymers are of the following types: (1) a dendrimer-like polymer having trivalent B atom at core and wedge point, a heteroatom such as O as linking unit (L), and di- to hexavalent group with mol. weight of ≥ 150 linking to the B atom via L, (2) a compound obtained by crosslinking of a multiarm polymer of $B(XRY)_3$ type [X = heteroatom; R = divalent group having mol. weight of > 150 (e.g., polyoxyethylene group); Y = polymerizable functional group], (3) a high-mol. compound bearing B atom preferably on side chain end or main chain end, and (4) high-mol. compound containing tetravalent B. The polymer electrolytes with improved charge-carrying ion capacities are obtained by mixing one or more types of the polymers above with an electrolyte salt such as a lithium salt and an aprotic solvent, e.g., carbonates, lactones, ether, etc., and can be used in batteries or capacitors. Thus, coupling a diol derived from ethylene oxide ring opening reaction with borane gave a 3-arm polymer, 1 g of which was combined with $LiBF_4$ at 1 mol/kg and 2.3 g γ -butyrolactone and cast coated on a glass surface to give a film of polymer electrolyte.

AB The electrolytes, for secondary Li batteries using Li **transition metal** oxide cathodes and anodes composed of graphite having interplanar spacing $d_{002} \leq 0.34$ nm, contain an additive having a redox potential 0.8-1.0 V high than the Li in the anode. The additive is preferably heterocyclic amide, carbamate, and/or sulfamide I, where X1-4 = C or N; Y = C1-12 acyl, ester, or **sulfonyl group**; R1-4 = H when X1-4 = N and do not exist when X1-4 = N.

AB The capacitor comprises (a) an electrode layer containing elec. conductive C, a soluble salt, a nonaq. **aprotic liquid solvent**, and a gel-forming polymer; and (b) an ionically conductive electrolyte layer in contact with the electrode layer, containing an alkali metal salt, the same polymer, and the same solvent. Such a solid electrode material is especially well adapted for use in multilayer capacitors in which such components can be made very thin, thereby providing a very low resistance for the device and permitting rapid discharge of the capacitor.

AB A Li battery contains a solid polymer electrolyte comprising a poly(vinyl
 chloride) network, a solute consisting of an alkali metal salt (e.g., LiClO₄,
 LiBF₄, LiAsF₆, LiCF₃SO₃, LiPF₆, and LiNCF₃SO₂) dissolved in ≥1 aprotic organic

solvent, and a low-b.p. solvent (especially, THF) than can be evaporated at .apprx.20°. The network optionally contains poly(vinyl acetate). The preferred aprotic organic solvent is propylene carbonate, ethylene carbonate, DMSO, tetramethylene sulfone, γ -butyrolactone, N-Me-2-pyrrolidinone, and tri- and tetra-ethylene glycol di-Me ether.

LANGUAGE: English

- AB The continuous-flow method with integrating observation was used to investigate irreversible electron-transfer reactions between neg. charged, substitution-inert **transition metal** complexes. Special attention was paid in order to distinguish between the different contributions to the energy of activation such as size of reactants, long-range charge interactions, influence of the free energy of reactions (difference in redox potential), and the composition (**electrolytic** content) of the **solns**. The electron-transfer reaction between $\text{Fe}(\text{CN})_6\text{Hxx-4}$ and IrCl_6^{2-} was selected to demonstrate the catalytic rate enhancement caused by the addition of mono-, di-, and trivalent cations. In the electron transfer reaction between Ag tetraphenylporphyrin tetrasulfonate and IrCl_6^{2-} , electron transfer occurs at the axial position of the complex, far away from the neg. charged **sulfonate groups**. A catalytic effect similar to that found in the reaction with $\text{Fe}(\text{CN})_6^{4-}$ is observed; this result precludes the cations having a bridge-like function during electron transfer. Monovalent cations of varying size show a maximum rate enhancement when their ionic radius is .apprx.0.23 nm. If long-range Coulomb interactions are shielded, and a situation in which the free energy change of reaction is zero is simulated, a maximum is extrapolated for the electron transfer rate constant of $10^{11}/\text{dm}^3/\text{mol}/\text{s}$.
